(54) Title: METHOD FOR THE PURIFICATION OF VIRUS

(57) Abstract

The utility of current recombinant adenovirus vectors for gene therapy applications is improved by designing targeted vectors capable of gene delivery to selected cell types *in vivo*. In order to achieve such targeting, incorporation of ligands in the adenoviral fiber protein, in which the protein mediates primary binding of adenovirus to its cell surface receptor, utilizes the HI loop of the fiber knob as a convenient locale for incorporation of heterologous ligands. Recombinant fiber proteins expressed in a variety of cells including baculovirus–infected insect cells and *E. coli* to demonstrate that the incorporation of the FLAG octapeptide into the HI loop does not ablate fiber trimerization and does not disturb formation of the cell–binding site localized in the knob. A recombinant adenovirus of the instant invention having this modified fiber shows that a short peptide sequence engineered in the knob is compatible with the biological functions of the fiber. A peptide incorporated into the knob according to the invention remains available for binding in the context of mature virions containing modified fibers. The invention incorporates heterologous ligands into the HI loop of the fiber knob and the properties of this locale are consistent with its employment in adenovirus retargeting strategies.

METHOD FOR THE PURIFICATION OF VIRUS

Field of the Invention

The instant invention relates generally to vectors and methods for gene therapy, and more particularly, to an adenovirus vector containing a heterologous peptide epitope

5   in the HI loop of the vector fiber knob and methods for purifying such a vector for application in transgene delivery.

Background of the Invention

Viruses, particularly adenoviruses have significant use as vectors for carrying genetic material into cells. Presently, adenoviral vectors are widely used in experimental

10   systems, and it is anticipated that they will soon have a significant use in a number of genetic therapies, both in humans and animals. In order to increase the efficiency of such viral-based genetic therapies, and to minimize the side effects resultant therefrom, the viral vectors must be concentrated and/or purified.

Recombinant adenovirus vectors have found wide employment for a number of

15   gene therapy applications (21, 35, 38). This fact has derived principally from the high levels of gene transfer achievable with this vector approach both *in vitro* and *in vivo*. Indeed, recombinant adenovirus vectors are distinguished from other available systems by their unique ability to accomplish *in situ* gene delivery to differentiated target cells in a variety of organ contexts (5, 6, 9, 10, 12, 20, 25, 27, 29, 31). Despite this property,

20   specific aspects of the adenovirus biology have prevented the full realization of the potential of such vectors. In this regard, the broad tropism profile of the parent virus for cells of diverse tissues potentially allows unrestricted gene delivery. Thus, for the many gene therapy applications requiring targeted, cell-specific gene delivery, the promiscuous tropism of the adenovirus vector represents a confounding factor. Based on this concept,

2

strategies to modify the native tropism of adenovirus have been developed to allow the

derivation of vectors capable of targeted gene delivery.

Strategies to achieve this end are directed at modifying specific steps in the

adenoviral infection pathway. Adenoviruses of serotypes 2 and 5 normally achieve initial

5   recognition and binding to target cells by means of interactions between the

carboxy-terminal knob domain of the fiber protein and the primary receptor (4, 17, 36).

After binding, RGD motifs in the penton base interact with cellular integrins of the $\alpha_V\beta_3$

and $\alpha_V\beta_5$ types (1-3, 37, 39, 40). This interaction triggers cellular internalization whereby

the virions achieve localization within the endosome. Acidification of the endosome

10   elicits conformational changes in capsid proteins, allowing their interaction with the

endosome membrane in a manner that achieves vesicle disruption and particle escape.

Following endosomolysis, the virion translocates to the nucleus, where the subsequent

steps of the viral life cycle occur. This understanding of the key role played by capsid

proteins in the viral infectious pathway has suggested strategies to alter this process via

15   modifications of these proteins.

In this regard, genetic retargeting of adenovirus vectors via modification of viral

genes encoding coat proteins, offers a simple way to achieve a significant improvement

in the present generation of these gene delivery vehicles. To this end, several groups

have reported genetic modifications to the knob domain of adenovirus fiber protein and

20   incorporation of such chimeric fibers into virions. For instance, workers in the art (35,

24) reported successful generation of Ad5 virions containing fibers consisting of the tail

and shaft domains of Ad5 fiber and the knob domain of Ad3, respectively. In addition,

Michael et al. (30) demonstrated the incorporation of the gastrin-releasing peptide into

the carboxy terminus of recombinant Ad5 fiber. This finding was extended by Legrand

3

et al. (30a) who achieved rescue of recombinant adenovirus vectors containing such

fibers. Another report published by Wickham et al. (41) described the generation of

recombinant virus containing fibers with carboxy-terminal polylysine sequences. These

studies have established key feasibility issues with respect to this genetic approach but

5   have also demonstrated a number of potentially limiting factors.

Of note, all the modifications of adenovirus fiber reported so far were directed

towards the carboxy terminus of the protein. In addition, these efforts were initiated

without prior knowledge of the three-dimensional (3D) structure of the fiber knob. Thus,

the employment of the carboxy terminus of the fiber represented a choice not fully

10   incorporating all relevant considerations. Clearly, 3D structural information has

important bearing upon the placement of heterologous protein sequences within the knob

for targeting purposes. In this regard, such localization of targeting ligands would ideally

be achieved in a manner to allow their surface presentation and to minimally perturb the

fiber quaternary structure. Thus, the recent crystallization of the fiber knob by Xia et al.

15   (43, 44) has provided a level of structural resolution potentially allowing such a rational

modification of the fiber protein. According to the proposed 3D model of the knob, the

HI loop possesses a number of features which predict its utility as an alternative site for

ligand incorporation. Specifically, the HI loop does not contribute to intramolecular

interactions in the knob, therefore incorporation of additional protein sequence should not

20   affect the trimerization of the fiber. In addition, the loop consists mostly of hydrophilic

amino acid residues and is exposed outside the knob. It thus potentially demonstrates a

high degree of flexibility, creating an optimal environment for ligand incorporation.

Furthermore, the lengths of HI loops vary significantly in knobs of different adenovirus

serotypes. This fact suggests that alterations of the original structure of the loop, such

as insertions and deletions, should be compatible with the correct folding of the entire

knob domain. Finally, the HI loop is not involved in the formation of the putative

cell-binding site localized in the knob.

Summary of the Invention

5   Based on these considerations, the instant invention develops a novel approach

to modifying the adenovirus fiber protein by employing the HI loop of the knob for this

purpose. This invention shows that it is possible to incorporate heterologous amino acid

sequences into the HI loop without affecting the correct folding of the fiber polypeptide

and its biological functions. Further, this locale offers advantages for strategies designed

10   to achieve tropism modification based upon genetic alteration of capsid proteins.

Presently employed techniques for the purification of adenoviral vectors are

based upon density centrifugation. This is an expensive and time consuming process.

If adenoviral vectors are to be produced in commercially significant quantities, there is

needed a low cost, rapid and simple method for their purification and concentration.

15   Such techniques should be compatible with presently employed manufacturing processes,

and should not require the use of complicated and/or expensive equipment.

Brief Description of the Drawings

Fig. 1 shows modifications of the HI loop of the fiber knob. PCR-based

mutagenesis was employed to delete a portion of the fiber gene encoding the

20   hypervariable region of the HI loop. A unique *EcoRV* restriction site was incorporated

in place of the deletion to allow the cloning of segments of DNA coding for heterologous

protein sequences. In the fiber-FLAG protein, deleted amino acids of the HI loop were

restored, and FLAG octapeptide was incorporated between threonine-546 and

proline-547. The site of deletion is indicated by a filled triangle.

5

Fig. 2 shows analysis of recombinant fiber proteins by polyacrylamide gel electrophoresis. Fiber proteins expressed in insect cells were analyzed by gel electrophoresis to confirm their trimeric configurations. To dissociate trimers to monomers, the proteins were denatured by boiling them in the sample buffer prior to

5   loading them on a 7.5% polyacrylamide gel. The bands were visualized by Coomassie blue staining. (A). Six-histidine-tagged fiber proteins purified on an Ni-NTA-Sepharose column. Lane 1, wild type fiber, boiled; lane 2, wild type fiber, unboiled; lane 3, fiber-FLAG, boiled; lane 4, fiber-FLAG, unboiled; lane M, broad-range protein standards. (B). Fiber-FLAG protein purified by immunoprecipitation with anti-FLAG

10   M2 affinity gel. Lane 1, unboiled protein; lane 2, boiled protein; lane M, broad-range protein standards. The numbers on the left indicate molecular masses of marker proteins in kilodaltons.

Fig. 3 shows inhibition of adenovirus infectivity by recombinant fiber proteins. HeLa cells were preincubated with either the wild-type (wt) fiber (A) or fiber-FLAG (B)

15   at the indicated concentrations for 10 min at room temperature. AdCMVLuc was then added at a multiplicity of infection of 10, and incubation was continued for another 30 min at room temperature. The unbound virus was aspirated, complete medium was added, and the cells were transferred to 37°C. After 30 h the cells were lysed and luciferase activity was determined. Luciferase activities are given as percentages of the

20   activity in the absence of blocking fiber protein. Each point represents the mean of four determinations obtained in one experiment.

Fig. 4 shows generation of Ad5F$_{HI}$FLAG. The master plasmid, pTG3602, was modified to incorporate a unique SwaI restriction site in the fiber gene, thereby creating plasmid pVK50, suitable for fiber modifications. The genome of Ad5F$_{HI}$FLAG was

6

generated by homologous DNA recombination in *E. coli* between the DNA fragment

containing the fiber-FLAG gene and plasmid pVK50 linearized by *SwaI* digestion. To

rescue the virus, the resulting plasmid, pVK300, which contains the complete adenoviral

genome with a modified fiber gene, was cleaved with *PacI* and was then used to transfect

5   293 cells.

Fig. 5 shows adenovirus binding assay results. Aliquots of A549 cells containing

10^5 cells per sample were incubated for 1 h at 4°C with serial dilutions of either wild-type

(wt) Ad5 fiber or fiber-FLAG (see Materials and Methods). Virions of Ad5CMVLacZ

(A) and Ad5F$_{HI}$FLAG (B) labeled with ^{125}I were added to samples, and incubation was

10   continued for an additional hour. The cells were washed with 4 ml of PBS containing

0.1% BSA and pelleted by low-speed centrifugation. Radioactivities of samples were

determined with a gamma counter. Each point represents the mean of two determinations

obtained in one experiment.

Fig. 6 shows accessibility of the FLAG peptide in the context of intact

15   Ad5F$_{HI}$FLAG virions. Virions of Ad5F$_{HI}$FLAG purified on a CsCl gradient were

dialyzed, immunoprecipitated with anti-FLAG M2-affinity gel as described herein, and

eluted from the gel with free FLAG peptide. Recombinant adenovirus vector

Ad5CMVLuc containing unmodified fiber was used as a negative control for binding.

Aliquots of all the fractions collected throughout the purification procedure were treated

20   with DNase I to digest traces of the cellular DNA and then treated with SDS, EDTA, and

proteinase K to release adenovirus DNA from the virions. The samples obtained were

analyzed on a 0.8% agarose gel, and DNA was detected by ethidium bromide staining.

Lanes 1 through 3, AdCMVLuc in the supernatant containing unbound material, buffer

wash, and FLAG-eluate, respectively; lanes 4 through 6, Ad5F$_{HI}$FLAG in the supernatant,

7

buffer wash, and FLAG-eluate, respectively. Lane M, DNA molecular weight standards (the bands corresponding to marker fragments ranging from 3 to 12 kb are seen on the gel).

Description of the Invention

5   The capsid of a gene therapy vector plays a significant role in targeting the type of host cell a vector will transfect. Modification regions exposed to the vector environment serves to direct a vector towards receptors specific to a well defined host cell population. Furthermore, such a modification also serves as a molecular recognition site for purification of modified vectors from a mixed population of vectors. While the

10   invention is described in reference to adenovirus capsid protein modification, to incorporate a heterologous epitope into the protein in order to ablate the inherent tropism of the virus, it is appreciated that the methods, protocols and reagents herein are broadly applicable to protein coated gene therapy vectors. Protein coated gene therapy vectors are defined herein to include viruses, virions, amd mono- and bi-layer micelles having

15   proteins attached thereto.

        Despite the numerous attempts which have been made to improve adenovirus as a vector for gene therapy applications, it still suffers from a number of important disadvantages, one of them being the promiscuous tropism of this virus. Genetic modification of adenovirus coat proteins to target novel cell surface receptors is the most

20   radical and, if successful, potentially the most efficient way to overcome this limitation. In this regard, fiber, penton base, and hexon proteins are candidates for such genetic modifications. While modifications of the penton base (42, 46) and the hexon (8, 11) have been reported, these alterations were limited to the introduction of short peptide sequences into the exterior domains of these components of the adenovirus virion. In

8

contrast, a larger number of studies have attempted functional modifications of the fiber protein. These attempts to modify the fiber protein have an obvious explanation: in contrast to the hexon and penton base proteins, the fiber protein mediates the primary interaction of the virus with its cognate cellular receptor and therefore dictates the

5 tropism of the virus. In addition, due to its rod-like structure, the fiber can optimally expose a novel binding ligand engineered into its structure, thus providing efficient binding to an alternative cellular receptor. Thus, alterations to the carboxy-terminal knob domain of the fiber normally containing the cell binding site is a logical approach to modifying viral tropism.

10   Since the time this idea was originally employed (31), several groups of investigators have proved its utility. To this end, recombinant adenoviruses containing chimeric Ad5-Ad3 (25, 37) fiber were derived, demonstrating the possibility of creating functional fiber chimeras. In addition, it was shown that by replacing the knob domain of the fiber one can alter the receptor specificity of the virus. Furthermore, in an elegant

15 study by Wickham et al. (45), addition of a carboxy-terminal polylysine sequence to the fiber polypeptide resulted in expanded tropism of the adenovirus vector. However, it should be noted that none of these efforts has addressed the goal of ablating the native tropism of the adenovirus vector; in these approaches, novel tropism distinct from the pre-existing natural tropism of the vector was engineered.

20   Until recently, the ability to accomplish the practical design of retargeted adenovirus vectors was limited by two major problems: lack of knowledge of the structure of the fiber knob domain and difficulty in manipulating the fiber gene in the context of the adenovirus genome. In this regard, publication of the 3D model of the Ad5 fiber knob by Xia et al. (47, 48) and the development of a novel genetic method by

9

Chartier et al. (7), which allow modification of virtually any region of the adenovirus genome, will dramatically facilitate efforts to retarget the adenovirus via alterations to the knob domain of the fiber. The instant invention derives from adenovirus vectors with modified fibers containing novel peptide ligands. Herein is described the utilization of

5   the HI loop of the fiber knob as an alternative site for incorporation of heterologous peptide sequences. According to the 3D model of the Ad5 fiber knob, the HI loop does not contribute to interactions within the knob which stabilize its trimeric configuration and is not involved in the formation of the receptor binding site. Importantly, due to the prevalence of hydrophilic amino acid residues in its primary sequence, the HI loop is

10   exposed outside the knob, thereby facilitating the interaction of potential ligand with the cellular receptor.

For initial proof of the concept, a FLAG coding sequence was incorporated into the region of the fiber gene corresponding to the HI loop and expressed this modified gene in baculovirus infected insect cells. An amino terminal six-His tag incorporated into

15   the design was used for simple chromatographic purification of recombinant fiber protein. Baculovirus-directed expression of this recombinant full size fiber was efficient, and according to our gel analysis and ELISA with the trimer-specific anti-fiber monoclonal antibody MAb, the product of expression was trimeric.

Previous success with bacterial expression of function and trimeric Ad3 and Ad5

20   fiber knobs (16, 21, 23, 31) could not be reproduced in attempts to generate modified knobs in *E. coli*. This also corresponds to the results obtained with bacterial expression of modified fiber knobs by other investigators (M. Mehtali, personal communication), suggesting that the adenovirus fiber knobs express in *E. coli* have limited utility and cannot be used as a molecular model for modifications of this domain of the fiber protein.

10

To further characterize the fiber-FLAG protein produced in insect cells, the accessibility of FLAG in the context of the fiber trimer was demonstrated. For this an assay was employed based on the specific interaction of FLAG-tagged proteins with M2-affinity gel containing anti-FLAG monoclonal antibody. This analysis confirmed

5   that the FLAG peptide is localized on the surface of the trimeric knob and is available for binding, thereby supporting the hypothesis about surface localization of the HI loop. By employing the fiber-FLAG chimera to block adenovirus infection it is shown that insertion of the FLAG peptide into the HI loop of the knob does not affect the correct folding of the cell binding domain localized in the knob. This is a significant finding

10   considering that the HI loop connects β-strands H and I, which are hypothesized to be involved in binding to the cellular receptor (38, 47, 48).

To incorporate fiber-FLAG chimeras into the adenovirus virion, a recombinant adenovirus genome was generated by using a novel method described recently (7). To reach this end, a master plasmid, pTG3602, from Transgene was modified to engineer a

15   vector which greatly facilitates modifications of the fiber gene in the adenovirus genome. By using this plasmid, it was possible to generate recombinant genome and rescued the virus of interest, Ad5F$_{HI}$FLAG. Importantly, this new virus is produced in high yields and demonstrates dynamics of infection identical to those of the wild type Ad5. Successful rescue of Ad5F$_{HI}$FLAG, as well as subsequent characterization of the virion,

20   confirmed our conclusions based on the results obtained with fiber-FLAG protein expressed in baculovirus-infected insect cells, thereby making baculovirus an expression system of choice for further fiber-modeling experiments.

Thus, it is shown that the HI loop of the fiber knob is a convenient site for incorporation of heterologous peptide ligands which may be successfully utilized in order

11

to target adenovirus vectors for gene therapy applications. This location in the knob can

be used either as an alternative site or in addition to carboxy-terminal modifications of

the fiber protein, offering a unique loop-like environment, which may be required for

proper biological functioning of some ligand sequences. For example, this structure may

5   be beneficial for peptide ligands obtained from phage display libraries containing random

peptide sequences flanked with two cysteine residues forming a disulfide bridge (23, 24).

In addition, ligands with the loop-like configuration may be less susceptible to

degradation by cellular carboxypeptidases than ligands positioned at the carboxy

terminus of the fiber. To realize the full potential of the HI loop for ligand incorporation,

10   recombinant adenoviruses containing different targeting moieties in this locale are

created. Generation of recombinant adenoviruses containing fibers with targeting ligands

incorporated into the HI loop of the knob will facilitate further efforts towards an

improved adenovirus vector for gene therapy applications. The successful use of the

FLAG epitope in binding experiments suggests that this or a similar purification tag can

15   be incorporated into an adenovirus virion to facilitate its purification. This simple

purification technique occurs at atmospheric laboratory pressure and does not require

expensive laboratory equipment such as ultracentrifuges or high pressure liquid

chromatography systems and can be easily scaled up if needed.

The present invention, provides a method for purifying and concentrating virus,

20   and the method is particularly suited for use with adenoviral vectors. In accord with the

method of the present invention, as will be described in further detail hereinbelow, an

adenoviral vector is modified so that its protein capsid expresses one or more

heterologous epitopes thereupon. These foreign epitopes distinguish the modified

adenovirus from the corresponding, unmodified virus and provide an active site which

12

is capable of binding to an antibody, chelating agent, other chemical reagent or the like. In accord with present invention, the modified virus is contacted with an appropriate binding reagent, which itself is preferably immobilized, as for example in a chromatography column. The modified virus is then bound and retained, and may be

5   collected by freeing from the agent.

For example, an appropriate binding reagent may be immobilized on a support medium in a column, and process liquid including the virus may then be flushed through the column. The column will selectively bind the modified virus, while permitting the unmodified virus, and other materials to pass therethrough. The modified virus may then

10   be eluted from the column by flushing with an appropriate reagent. In this manner, a purified, concentrated sample of the adenoviral vector is obtained.

The protein capsid of the virus is preferably modified by utilizing a plasmid to insert genetic information into the adenovirus to cause it to express the heterologous epitope thereupon. In some instances, modification of the capsid will be at a carboxy

15   terminal of the capsid fibers. In other instances, the modification will take place at the knob domain of the fiber; most preferably at the H-I loop of the knob domain.

In one particular series of experiments, a plasmid vector designated pTG3602S is utilized to generate recombinant adenoviral genomes which contain genes encoding: fiber-short linker-RGS6H; fiber-short linker-somatostatin; in the capsids of adenovirus.

20   This sequence was expressed at the C-terminus of the capsid fiber of an adenovirus designated Ad5FcRGS6H. The presence of the modified fiber gene in the viral genome was confirmed by a cycle sequencing readout on viral DNA isolated from purified virions. The presence of C-terminal modifications in the fibers was confirmed by Western blot analysis carried out on purified virus.

13

It was found that the RGS6H tag engineered into the fiber is accessible to anti-RGS4H monoclonal antibodies. This was confirmed in an experiment in which the viral lysate was loaded on a Ni-NTA column. The column was first washed with 40mM imidazole to flush unbound virus therefrom. The column was then developed with 0.5M

5   imidazole to elute the modified virus therefrom. A different viral material, namely AdCMV-Luc was added to the column as negative control material, and treated as above. All samples from the column experiments were lysed with SDS to release viral DNA, and analyzed by agarose electrophoresis. The analysis showed that AdCMV-Luc did not adhere to the column and was washed therefrom by the 40mM imidazole, but that the

10   Ad5FcRGS6H modified virus bound to the column and was only eluted therefrom by the 0.5M imidazole. The foregoing demonstrates that plasmids may be employed to modify the capsid of a virus to produce a heterologous epitope thereupon, and that this modified virus may be separated from other virus by use of an affinity reagent.

It is to be understood that within the general principles of this invention, the

15   adenovirus vector may be made to selectively bind to an appropriate affinity reagent, by modifying the protein capsid thereof so as to cause the capsid to have a novel epitope thereupon. In this manner, the virus may be selectively separated from unmodified virus, and other materials. The methodology of the present invention may be employed to collect, concentrate and purify viral materials through a process which is simple, low cost

20   and reliable. Furthermore, the process is compatible with standard techniques used to prepare adenoviral vectors. Consequently, the present invention greatly facilitates the production of materials for a variety of genetic therapies.

The following examples are given for the purpose of illustrating various embodiments of the invention and are not meant to limit the instant invention.

14

Example 1 - Cells.

293 cells (16) obtained from Microbix (Toronto, Ontario, Canada) and HeLa

human adenocarcinoma cells and A549 human lung carcinoma cells obtained from

American Type Culture Collection (Rockville, Md.) were maintained in Dulbecco's

5   modified Eagle's medium (DMEM)-Ham's F12 from Mediatech (Herndon, Va.)

supplemented with 10% fetal calf serum (FCS) (Hyclone Laboratories, Logan, Utah) at

37°C and 5% CO_2.

Example 2 - Enzymes.

Restriction endonucleases, T4 DNA ligase, T4 polynucleotide kinase, and

10   proteinase K were from either New England Biolabs (Beverly, Mass.) or Boehringer

Mannheim (Indianapolis, Ind.).

Example 3 - Protein assay.

The concentrations of purified proteins were determined by the Bradford protein

assay (Bio-Rad, Hercules, Calif.) with bovine gamma globulin as the standard.

15   **Example 4 - Antibodies.**

Anti-fiber monoclonal antibodies 4D2 (19) and 1D6.14 (14) were generated at the

University of Alabama at Birmingham Hybridoma Core Facility. Anti-FLAG monoclonal

antibody M2 and M2-affinity gel were purchased from Scientific Imaging Systems

(Eastman Kodak, New Haven, Conn.)

15

Example 5 - Constructi n of recombinant plasmids.

To generate a gene encoding the Ad5 fiber knob domain with the HI loop deleted,
a PCR technique was employed. Two pairs of primers F1 (5' TAAGGATCCG
GTGCCATTAC AGTAGGAAAC AAAAATAA 3') and R1 (5' CATAGAGTAT

5   GCAGATATCG TTAGTGTTAC AGGTTTAGTT TT G 3'), and F2 (5' GTAACACTAA
CGATATCTGC ATACTCTATG TCATTTTCAT GG 3') and R2 (5' CCCAAGCTTA
CAATTG AAAA ATAAACACGT TGAAACATAA C 3'), were used to amplify
portions of the fiber gene corresponding to positions 1159 to 1451 and 1642 to 1747,
respectively. In addition, the second fragment also contains 43 bp of Ad5 DNA adjacent

10   to the 3' end of the fiber gene in the viral genome. The fragments generated were then
gel purified, mixed, and joined by the third PCR using primers F1 and R2. The product
obtained contains a unique *EcoRV* restriction site in place of the deleted portion of the
sequence encoding the HI loop, as well as *BamHI* and *HindIII* sites inserted into the ends
of the molecule to facilitate subsequent cloning. This DNA fragment was cleaved with

15   *BamHI* and *HindIII* and cloned into the *BamHI-HindIII*-digested bacterial expression
vector pQE30 (Qiagen, Santa Clara, Calif.), resulting in plasmid pQE.KNOBΔHI.

To construct an expression plasmid with the FLAG sequence incorporated into
the HI loop of the fiber, oligonucleotides TACACTAAAC GGTACCCAGG AAACAGG
AGA CACAACTGACT ACAAGGA CGACGATGACAAG CC and GGCTTGTCATC

20   GTCGTCCTTG TA GTCAGTTGT GTCTCCTG TTT CCTGGGTACCG TTTAGTGTA
were annealed to form a duplex and cloned into *EcoRV*-digested pQE.KNOBΔHI. The
plasmid containing the duplex in the correct orientation was designated
pQE.KNOB$_{HI}$FLAG.

The transfer plasmids for the generation of recombinant baculoviruses expressing

chimeric fibers were made as follows: a *BglII-MfeI* fragment from pQE.KNOB$_{HI}$FLAG

was utilized to replace the *BglII-MfeI* fragment in the vector pBS.F5.UTR which has been

described previously (24), thereby generating pBS.F5$_{HI}$FLAG. A *BssHII-XhoI* fragment

5   from pBS.F5$_{HI}$FLAG was then cloned into the *BssHII-XhoI*-digested baculovirus transfer

vector pFastBac1 (Life Technologies, Gaithersburg, Md.), resulting in pFB.F5$_{HI}$FLAG.

To introduce the six-His purification tag into the amino terminus of the chimeric fiber,

the *BamHI-BssHII* fragment of pFB.F5$_{HI}$FLAG was replaced with a synthetic duplex

made with oligonucleotides GATCCATGCA TCACCATCAC C ATCACAAG and

10   CGCGCTTGTG ATGGTGATGG TGATGCATG, which encodes MetHis$_6$Lys. The

resultant plasmid, pFB6H.F5$_{HI}$FLAG, contains the gene coding for a fiber with an

amino-terminal six-His tag and FLAG peptide inserted into the HI loop. To derive a

similar plasmid containing the fiber gene with the HI loop coding sequence unmodified,

the *BssHII-MfeI* fragment in pFB6H.F5$_{HI}$FLAG was replaced with homologous fragment

15   from pNEB.PK3.6 (24), generating pFB6H.F5.

In order to clone the gene encoding the fiber with the FLAG sequence in the HI

loop into the fiber shuttle vector pNEB.PK3.6, a *BstXI-MfeI* fragment of the wild type

fiber gene contained in this plasmid was replaced with a *BstXI-MfeI* fragment from

pQE.KNOB$_{HI}$FLAG, thereby creating pNEB.F5$_{HI}$FLAG.

20   To facilitate the generation of recombinant adenovirus genomes by homologous

recombination in *Escherecia coli*, plasmid pTG3602 (7), obtained from Transgene

(Strasbourg, France), was engineered to create a specialized vector suitable for

modifications of the fiber gene. To accomplish this end, an *NdeI* site localized in the

fiber gene was employed. Plasmid pTG3602 was partially digested with *NdeI* and ligated

with an *NdeI-SwaI* linker, TACCCATTTAAATGGG. This plasmid, containing a *SwaI*

site in the fiber gene was designated pVK50.

A recombinant adenovirus genome containing a gene encoding the fiber-FLAG

protein was generated by homologous DNA recombination in *E. coli* BJ5183 between

5   pVK50 linearized with *SwaI* and the 3-kb EcoRI fragment from pNEB.F5$_{HI}$FLAG

containing the gene of interest, as described by Chartier et al. (7). The newly generated

genome was then excised from the resultant plasmid, pVK300, and employed to rescue

the virus.

Example 6 - Viruses.

10   Ad5 vectors, AdCMVLuc and AdCMVLacZ, which express firefly luciferase and

bacterial β-galactosidase (18), respectively, were obtained from R. D. Gerard, the

University of Texas Southwestern Medical Center, Dallas, Tex.

Ad5F$_{HI}$FLAG was generated by transfection of 293 cells with *PacI*-digested

pVK300, as previously described (7).

15   Adenoviruses were propagated on 293 cells and purified by centrifugation in CsCl

gradients according to a standard protocol (15). Determination of virus particle titer was

accomplished spectrophotometrically by the method described by Maizel et al. (28), with

a conversion factor of 1.1×10^{12} viral particles per absorbance unit at 260 nm. To

determine the titer of infectious viral particles on 293 cells, a plaque assay was employed

20   as described by Mittereder et al. (32).

Recombinant baculoviruses expressing chimeric fibers were generated with a

Bac-to-Bac expression kit from Gibco-BRL (Life Technologies) according to the

manufacturer's protocol.

18

Example 7 - Expressi n and purification f six-His-tagged recombinant proteins.

Recombinant fibers were expressed in *Spodoptera frugiperda* Sf9 cells infected with recombinant baculovirus by the method recommended for the Bac-to-Bac system (Life Technologies). Recombinant proteins were then purified by immobilized metal ion

5   affinity chromatography on Ni-nitrilotriacetic acid (NTA)-Sepharose (Qiagen) by following recommendations from the manufacturer.

Example 8 - ELISA.

In order to characterize recombinant fiber proteins, an enzyme-linked immunosorbent assay (ELISA) was employed. The six-His tagged fibers were

10   immobilized on Ni-NTA HisSorb Strips (Qiagen) essentially as described in the Qiagen manual. 200 μl of fiber protein solution at a concentration 1 μg/ml was added to each well of an Ni-NTA HisSorb Strip and incubated for 1 h at room temperature. After incubation the wells were washed four times with phosphate-buffered saline (PBS)-Tween buffer, and 200 μl of anti-fiber antibody (1:2000 dilution) or anti-FLAG

15   antibody (1:140 dilution) was added. Following incubation at room temperature for 2 h the wells were washed again and incubated with 1:10,000 dilution of goat anti-mouse immunoglobulin G conjugated to horseradish peroxidase (HRP) for 45 min. The wells were then washed four times with PBS-Tween buffer and developed with 2',2'-azino-bis(3-ethylbenzthiazoline-6-sulfonic acid) (ABTS) (diammonium salt). The

20   ABTS-HRP reaction was read in a microtiter plate reader set at 405 nm.

Example 9 - FLAG accessibility assay.

To demonstrate the binding of the FLAG-tagged fiber protein incorporated into intact virions of $Ad5F_{HI}FLAG$ to anti-FLAG M2 monoclonal antibody, an immunoprecipitation assay was employed. $Ad5F_{HI}FLAG$ or AdCMVLuc purified on

5 CsCl gradients were dialyzed against HEPES buffer (10 mM HEPES, 1 mM $MgCl_2$, 10% glycerol, [pH 7.4]) and absorbed onto M2-affinity gel (Eastman Kodak) as follows. Fifty microliters of dialyzed virus containing 10^{11} viral particles was mixed with 100 μl of M2-affinity gel equilibrated with HEPES buffer containing 50 mM NaCl and 0.5% bovine serum albumin (BSA) and then incubated overnight at 4°C on a rotating wheel.

10 Following incubation, the gel was spun down by brief centrifugation in a microcentrifuge. The supernatant was collected for further analysis and the gel was washed with 0.5 ml of Tris-buffered saline (TBS). Virus was eluted at 4°C with 50 μl TBS containing 400μg of FLAG peptide per ml. The supernatant containing unbound material, the wash, and the eluate were then employed to detect the presence of the virus.

15 For this, aliquots of these fractions were treated for 1 h at 37°C with sodium dodecyl sulfate, EDTA, and proteinase K at final concentrations of 1%, 10 mM and 100 μg/ml, respectively. The samples were analyzed by agarose gel electrophoresis to detect viral DNA.

Example 10 - Purification of the fiber-FLAG protein by immunoprecipitation.

20 The recombinant fiber-FLAG protein was expressed in baculovirus infected Sf9 cells as follows. For large scale expression of the fiber-FLAG protein, monolayers of Sf9 cells in T75 flasks were infected with recombinant baculovirus at multiplicity of infection of 5 to 10 and then were incubated at 28°C until a complete cytopathic effect was

20

observed. At 2 to 3 days postinfection, the cells were scraped, pelleted by low speed

centrifugation, and resuspended in lysis buffer (50 mM Tris-HCl pH 8.0, 150 mM NaCl,

1% Nonidet P40, 0.1% SDS, 0.02% sodium azide, 100 μg/ml phenylmethylsulfonyl

fluoride, 1 μg of aprotinin per ml). The cells were then incubated on ice for 30 min. The

5   lysate was cleared by centrifugation at 12,000 x g for 5 minutes in a microcentrifuge.

The cleared lysate was mixed with the slurry of M2 affinity gel, and the rest of the

procedure was performed as described above for immunoprecipitation of Ad5F$_{HI}$FLAG.

Example 11 - Trimerization assay of recombinant proteins.

To determine whether the fiber proteins expressed in baculovirus infected insect

10   cells could form trimers, these proteins were analyzed by SDS-polyacrylamide gel

electrophoresis as previously described (30).   Proteins were either boiled prior to

electrophoresis, to dissociate the trimers, or loaded on the gel without denaturation. The

trimeric or monomeric configuration of these molecules was thus determined based on

their mobilities in the gel.

15   **Example 12 - Inhibition of virus mediated gene transfer by recombinant fiber**
proteins.

The ability of the fiber-FLAG chimera to block adenovirus-mediated gene

transfer was evaluated in infection inhibition experiments similar to those described

previously (17, 24, 34, 36). Briefly, monolayers of HeLa cells grown in a 24-well plate

20   were preincubated at room temperature with serial 10-fold dilutions of either wild type

fiber or fiber-FLAG protein prior to infection with a replication defective recombinant

adenovirus expressing firefly luciferase, AdCMVLuc. Unbound virus was washed, and

the cells were incubated at 37°C to allow internalization of AdCMVLuc and expression

21

of the luciferase gene. A luciferase assay of the lysates of infected cells was performed

30 h postinfection with a luciferase assay system from Promega (Madison, Wis.).

Example 13 - Virus binding assay.

Human lung carcinoma A549 cells grown in T75 flasks and then harvested with

5   EDTA, washed once with PBS, pelleted and resuspended to a final concentration of 10^7

cells/ml in DMEM-Ad medium (DMEM, 20mM Hepes, 0.5%BSA) as described by

Wickham et al (45). One-hundred-microliter aliquots of the cells were transferred to 5

ml test tubes and incubated for 1 h at 4°C with 100 μl of recombinant fiber diluted in

DMEM-Ad medium.

10   The recombinant adenoviruses AdCMVlacZ and Ad5F$_{HI}$FLAG were purified on

a CsCl gradient and dialyzed against buffer containing 10 mM HEPES, 1 mM MgCl2,

10% glycerol [pH 7.4]. Aliquots of both viruses containing 50 μg of viral protein were

labeled with ^{125}I using IODO-BEADS iodination reagent (Pierce, Rockford, Ill.) as

previously described (20). Labeled viruses were purified from unincorporated ^{125}I by gel

15   filtration on PD-10 columns (Pharmacia, Piscataway, N.J.). Fifty-microliter aliquots of

labeled virions with total radioactivities of 10^5 cpm were then added to A549 cells

preincubated with fiber dilutions or PBS and incubated at 4°C for another hour.

The samples were diluted with 4 ml of PBS containing 0.1% BSA, and the cells

were pelleted by centrifugation. Supernatant containing unbound virus was aspirated,

20   and the radioactivities of cell pellets were determined in a gamma counter.

22

Example 14 – Expression of recombinant fiber knobs in _E. coli._

To test the concept of the suitability of the HI-loop of the fiber knob for

incorporation of heterologous protein sequences, recombinant knob proteins expressed

in _E. coli_ were employed. Previously such recombinant knobs produced by bacterial cells

5   were successfully utilized for a variety of applications (Gerard, McCleland, Louis,

Krasnykh). To achieve this aim, a PCR approach was used to derive a gene encoding

Ad5 fiber knob with a partial deletion in the HI-loop. This deletion was engineered to

remove amino acids TLNGTQETGDTTP from the HI-loop of the knob, and to introduce

unique EcoRV site in place of deleted sequence, thereby facilitating the cloning of

10   alternative sequences in this region (Figure 1). The deletion made removed the portion

of the HI-loop which varies most significantly in the fiber knobs of different serotypes

of human adenoviruses. The sequence generated by PCR contained an open reading

frame corresponding to two segments of the fiber protein including amino acids glycine-

387 through isoleucine-534 and serine-548 through glutamine-581 (here and in the

15   following text the coordinates are given according to the wild type Ad5 fiber protein

sequence). This sequence was cloned into bacterial expression vector, pQE30, thereby

creating a fusion gene encoding the deleted fiber knob and containing amino terminal

6His purification tag. The newly generated plasmid, pQE.KNOBΔHI, was then utilized

as a cloning vector to incorporate fragments of DNA encoding cleavage sites for highly

20   specific proteolytic enzymes: Factor Xa, thrombin and enterokinase. These recognition

sequences were chosen as probes to evaluate the accessibility of the selected portion of

the HI-loop. Therefore, using pQE.KNOBΔHI expression plasmids pQE.KNOB$_{HI}$F-Xa,

pQE.KNOB$_{HI}$THR and pQE.KNOB$_{HI}$FLAG, containing genes were generated which

encoded knobs with cleavage sites for Factor Xa, thrombin and enterokinase,

23

respectively. By incorporating these sequences in the ORF of the knob the previously

deleted codons were restored. Therefore in the final constructs the cleavage sequences

for aforementioned proteolytic enzymes were introduced as insertions between threonine-

546 and proline-547. These expression plasmids were then utilized to direct expression

5   of recombinant knob proteins in *E. coli* cells.

In contrast to the wild type Ad5 knob used in our previous study ((21)), all

recombinant knobs with insertions of proteolysis sites in the HI-loop, as well as the one

with a partially deleted loop sequence, showed very low levels of expression

corresponding to less than 5% of the yield of the wild type knob. Moreover, with the

10   exception of the knob containing Factor Xa cleavage site, these knobs failed to trimerize

(data not shown). Preparations of the knob with Factor Xa recognition sequence

contained trimers in the amount of 95% of total protein purified, the rest being

monomeric molecules. However, these trimers were gradually converting to monomers

with the half life of 7 days when stored at 4°C, making it difficult to use this recombinant

15   protein for subsequent experiments. In addition, none of the proteins produced was

susceptible to the cleavage with relevant protease under a variety of different conditions.

These data have demonstrated that recombinant Ad5 fiber knob expressed in *E.*

coli cells is not an appropriate model for experiments involving modifications of its

amino acid sequence.

20   **Example 15 - Characterization of recombinant fibers expressed in baculovirus**
infected insect cells.

To test the concept of the suitability of the HI loop of the fiber knob for

incorporation of heterologous protein sequences, we first employed recombinant fiber

proteins expressed in a baculovirus expression system. This system has already proved

24

its utility for the expression of functional Ad2, Ad3, and Ad5 fiber proteins, as well as Ad3-Ad5 and Ad5-Ad3 fiber chimeras (13, 26, 33, 37).

To achieve this aim, a PCR approach was used to derive a gene encoding the Ad5 fiber knob with a partial deletion in the HI loop. This deletion was engineered to remove 5 amino acids TLNGTQETGDTTP from the HI loop of the fiber knob domain and to introduce a unique *EcoRV* site in place of the deleted sequence, thereby facilitating the cloning of alternative sequences in this region (Fig. 1). The deletion removed the portion of the HI loop which varies most significantly in the fiber knobs of different serotypes of human adenoviruses. The sequence generated by PCR contained an open reading 10 frame corresponding to two segments of the fiber protein including amino acids glycine-387 through isoleucine-534 and serine-548 through glutamine-581 (coordinates given are according to those of the wild type Ad5 fiber protein sequence). This sequence was cloned into the plasmid vector pQE30. The newly generated plasmid, pQE.KNOBΔHI, was then utilized as a cloning vector to incorporate a fragment of DNA 15 encoding the FLAG octapeptide (DYKDDDDK), which has been widely used as a detection and purification tag in a variety of studies. Thus, this FLAG peptide was chosen in fiber constructs as a probe to determine whether a heterologous peptide sequence incorporated into the HI loop of the knob was accessible in the context of a trimeric fiber molecule. By incorporating this sequence into the open reading frame of 20 the knob, the previously deleted condons were restored. Therefore, in the newly generated plasmid, pQE.KNOB$_{HI}$FLAG, the FLAG coding sequence was introduced as insertions between threonine-546 and proline-547. This plasmid was then employed to construct a full-size recombinant fiber gene in a baculovirus transfer vector. A similar transfer plasmid containing the wild type fiber gene was designed for control purposes.

25

In order to facilitate subsequent purification of the expression products, we introduced

into the designs of both genes a sequence encoding an amino-terminal six-His tag. These

plasmids were then utilized to generate two recombinant baculoviruses containing fiber

genes encoding wild type Ad5 fiber and a fiber protein containing FLAG peptide in the

5   HI loop of the knob domain.

Recombinant fibers were recovered from the lysates of baculovirus-infected insect

cells with Ni-NTA-Sepharose designed for purification of the six-His-tagged proteins.

The yield of purified fibers was in the range of 10 μg of protein per 10^6 infected cells.

Analysis by SDS-polyacrylamide gel electrophoresis of both recombinant proteins

10   showed that they formed stable trimers which, when boiled in the gel loading buffer,

dissociated into monomers of the expected molecular mass of 63 kDa (Fig. 2A). This

result demonstrated that the incorporation of a short peptide sequence in the HI loop of

the knob does not ablate trimerization of the fiber. Therefore, by using the baculovirus

expression system we were able to obtain preparative amounts of the recombinant fibers

15   of interest which were suitable for subsequent assays.

Example 16 – Accessibility of the FLAG peptide in the context of trimeric fiber.

To find out whether the FLAG peptide introduced into the HI loop of the fiber

was available for binding, an assay was used based on the specific interaction of the

FLAG-tagged proteins with an affinity matrix containing anti-FLAG monoclonal

20   antibody. For these experiments, the recombinant fiber protein with the FLAG sequence

in the HI loop (fiber-FLAG) was purified on an Ni-NTA-Sepharose column and then

immunoprecipitated with M2-affinity gel. Protein bound to the matrix was then

specifically eluted with FLAG peptide and analyzed on an SDS containing

26

polyacrylamide gel (Fig. 2B). According to this analysis, the fiber-FLAG protein

efficiently bound to M2-affinity gel, demonstrating the availability of the FLAG epitope

for interaction with an anti-FLAG monoclonal antibody in the context of the trimeric

fiber molecule. Importantly, this interaction did not affect the stability of the trimer,

5   suggesting that a recombinant virion containing a novel ligand incorporated in the HI

loop of the fiber knob will maintain its structural integrity throughout the binding step

of the infection.

**Example 17 - Inhibition of adenovirus infection by recombinant fiber-FLAG
protein.**

10   A fiber-FLAG recombinant protein was employed to block adenovirus infection

in the in vitro setting. This established assay is based on the fact that recombinant

adenovirus fiber proteins are capable of blocking infection by the adenovirus from which

they were derived. In addition, this inhibition of viral infection takes place in a dose

dependent manner.

15   In experiments, HeLa cells seeded in 12-well tissue culture plates were

preincubated with various concentrations of the wild-type Ad5 fiber or fiber-FLAG

protein prior to infection with the recombinant Ad5 vector AdCMVLuc, which expresses

firefly luciferase as a reporter. Previously, it was shown that this assay, based on gene

transfer by the viral vector, generates data correlating well with a classic binding assay

20   accomplished with radiolabeled virus (24). Thirty hours postinfection, the cells were

lysed and the lysates were utilized for the luciferase activity assay (Fig. 3). According

to this assay, both fiber proteins blocked infection by AdCMVLuc in a dose dependent

manner and demonstrated identical profiles of infection inhibition. These data confirmed

that incorporation of heterologous peptide sequences into the HI loop of the fiber knob

does not affect the correct folding of the cell-binding site formed by the carboxy-terminal
portion of the fiber protein.

Example 18 - Characterization of the fiber-FLAG protein by ELISA.

        To obtain additional evidence supporting the functional utility of the fiber-FLAG

5   protein, this recombinant protein by ELISA was analyzed, employing several monoclonal

antibodies specific for the FLAG epitope and different conformations of the Ad5 fiber.

To achieve this end, wild type fiber and fiber-FLAG proteins expressed in insect cells

were absorbed on HisSorb ELISA strips covered with Ni-NTA (Qiagen) and probed with

anti-fiber antibody 4D2 or 1D6.14 or anti-FLAG antibody M2. Antibody 4D2 reacts with

10   Ad5 fiber monomers and trimers and was used in this assay as a positive control, whereas

antibody 1D6.14 binds to an as yet unidentified conformational epitope in the fiber knob

and is trimer specific. The ELISA strips were then developed with goat anti-mouse

antibody-HRP conjugate.

        As seen in Table 1, both fiber proteins efficiently reacted with anti-fiber

15   antibodies 4D2 and 1D6.14, thereby suggesting that the 3D structure of the knob in the

fiber-FLAG molecule is identical to that of the wild type fiber. In addition, the

fiber-FLAG chimera specifically reacted with anti-FLAG antibody M2, confirming the

availability of this epitope for binding in the context of a trimeric fiber molecule. Thus,

these results validated the data generated earlier by gel electrophoresis analysis of

20   Ni-NTA- or M2-affinity gel purified fiber-FLAG protein, providing the rationale for the

incorporation of the fiber-FLAG chimera into the adenovirus virion for further

characterization.

28

Example 19 - Generati n of Ad5F$_{HI}$FLAG.

Despite the fact that the data obtained with the recombinant fiber-FLAG protein

supported the concept of its functional utility in the context of the adenovirus virion, only

successful generation of the recombinant virus would prove our hypothesis regarding the

5   compatibility of the modifications of the HI loop of the fiber knob with viral functions.

Therefore, the task of incorporating the fiber-FLAG chimera into the adenovirus virion

was undertaken.

In order to derive this virus, a novel genetic method based on homologous DNA

recombination in *E. coli* cells was utilized (7).   In brief, this method involves

10   recombination between two linear DNA molecules cotransformed into bacterial cells to

generate a recombinant adenovirus genome.   One of these molecules is plasmid

pTG3602, or its derivative, containing the full-size adenovirus genome cloned in the

bacterial vector and flanked with two *PacI* sites.   The second partner in this

recombination scheme is the genetic construct of interest flanked with two segments of

15   adenovirus genomic DNA which dictate the localization of this construct in the

adenovirus genome generated as a result of the recombination. This DNA sequence can

be either a transgene or the original Ad5 gene, modified by traditional methods of genetic

engineering in the context of small recombinant plasmids. To reduce the nonrecombinant

background generated by pTG3602, prior to transformation this plasmid was cleaved

20   with a restriction enzyme within or near the region of the genome where the final

construct was going to be inserted. Although this method has numerous advantages

compared to traditional generation of recombinant adenovirus genomes by homologous

recombination in mammalian cells, it requires the existence of unique restriction sites

within the regions of the adenovirus genome to be modified. However, Ad5 genomic

29

DNA in pTG3602 does not contain any unique restriction sites in the fiber gene, which

limits its utility for modifications of fiber. Thus, to overcome this limitation, this plasmid

was modified by inserting a unique cleavage site for the restriction endonuclease *SwaI*

into the fiber gene. To this end, one of the two *NdeI* sites present in Ad5 DNA and

5   localized 47 bp downstream from the fiber gene's 5' end was converted into *SwaI* site by

insertion of an *SwaI*-linker (Fig. 4). The plasmid generated, pVK50, was then utilized

for homologous recombination with the fragment of DNA containing the gene encoding

fiber-FLAG flanked with viral DNA adjacent to the fiber gene in the Ad5 genome. As

a result of this recombination, a plasmid, pVK300, containing a modified fiber gene in

10   the context of the complete adenovirus genome was derived. Adenovirus DNA was

released from pVK300 by *PacI* digestion and used for transfection of 293 cells to rescue

the virus as described previously (7).

DNA isolated from CsCl gradient-purified virions of the newly generated virus,

Ad5F_{HI}FLAG, was subjected to PCR analysis and cycle sequencing to confirm the

15   presence of the FLAG coding sequence in the fiber gene incorporated in the genome.

According to both analyses, Ad5F_{HI}FLAG indeed contained the fiber gene of interest.

Example 20 - Characterization of Ad5F_{HI}FLAG by a cell-binding assay.

The yield of this virus grown on 293 cells, approximately 10^{11} plaque forming

units (PFU) per preparation obtained from 20, 75 cm^2 tissue culture flasks, was

20   comparable to what we normally obtain when growing the wild-type Ad5. Also, we did

not see any delay in plaque formation dynamics either when rescuing the virus or when

expanding it. These observations suggested that the introduction of the FLAG peptide

in the HI loop of the knob did not significantly affect the correct folding of the fiber

molecule and its biological functions.

In order to prove this, radiolabeled Ad5F$_{HI}$FLAG was employed to investigate its

ability to bind the fiber receptors on the cell surface. In this assay ^{125}I-labeled

5   Ad5F$_{HI}$FLAG was allowed to bind A549 human lung carcinoma cells, which are known

to express high levels of Ad5 fiber receptors. Baculovirus expressed wild type Ad5 fiber

and fiber-FLAG were used as competitors to selectively block cellular receptors and

inhibit virus binding. The recombinant adenovirus vector Ad5CMVLacZ containing wild

type fibers was used as a control. The results of this experiment showed both viruses

10   demonstrate identical dose responses when competing with fibers of either type. Thus,

incorporation of the heterologous peptide in the HI loop of the fiber-FLAG protein did

not have any negative effect on the formation of the cell binding site localized in the knob

and, therefore, did not affect virus infectivity.

Example 22 - Characterization of Ad5F$_{HI}$FLAG by antibody binding.

15   Since the ultimate goal of our strategy is engineering of a targeting ligand into the

knob, it was necessary to determine whether such a ligand would be available for

interaction with its target cell surface receptor after incorporation into the adenoviral

virion. To this end, the FLAG sequence incorporated into the fiber of Ad5F$_{HI}$FLAG was

employed to test the accessibility of the HI-loop of the knob in a context of intact

20   adenoviral particle. This was accomplished in an assay similar to the one used to

evaluate FLAG accessibility in the recombinant fiber-FLAG protein expressed in insect

cells. Virions of purified on CsCl gradient were dialyzed against Hapes buffer and

incubated with M2 affinity gel to allow interaction between FLAG peptide and anti-

31

FLAG monoclonal antibody conjugated to the gel matrix. Similarly prepared virons of AdCMVLuc containing wild type fibers were utilized in this experiment as a negative control. After incubation the buffer containing unbound material was collected and the gel was washed with the buffer to remove the traces of free virus. Finally, the viruses

5   were eluted from the gel by soluble FLAG peptide. Aliquots of the samples collected were treated with proteinase K to release viral DNA from virions which was then visualized by agarose gel electrophoresis (Figure 5). As expected, virons of AdCMVLuc did not react to M2 antibody and were detected only in the fraction containing unbound virus and in the wash. In marked contrast, $Ad5F_{HI}FLAG$ particles efficiently bound to

10   the affinity gel, since viral DNA was present exclusively in FLAG peptide eluate. Thus, establishing that heterologous ligand sequence engineered into the HI-loop of the knob domain of the fiber incorporated in intact Ad5 virion remains accessible for interaction with the relevant receptor structure, thereby providing a rationale for generation of genetically targeted adenoviral vectors on this basis.

15   **Example 22 - FLAG accessibility in the context of the $Ad5F_{HI}FLAG$ virion.**

To insert a targeting ligand into the knob, it was necessary to determine whether such a ligand would be available for interaction with its target cell surface receptor after incorporation into the adenovirus virion. To this end, the FLAG sequence incorporated into the fiber of $Ad5F_{HI}FLAG$ was employed to test the accessibility of the HI loop of the

20   knob in the context of an intact adenovirus particle. This was accomplished in an assay similar to the one used to evaluate FLAG accessibility in the recombinant fiber-FLAG protein expressed in insect cells. Virions purified on a CsCl gradient were dialyzed against HEPES buffer and incubated with M2-affinity gel to allow interaction between

32

the FLAG peptide and an anti-FLAG monoclonal antibody conjugated to the gel matrix.

Similarly prepared virions of AdCMVLuc containing wild-type fibers were utilized in

this experiment as a negative control. After incubation, the buffer containing unbound

material was collected and the gel was washed with the buffer to remove the traces of free

5   virus. Finally, the viruses were eluted from the gel with soluble FLAG peptide. Aliquots

of the samples collected were treated with proteinase K to release viral DNA from

virions, which was then visualized by agarose gel electrophoresis (Fig. 7). As expected,

virions of AdCMVLuc did not react with M2 antibody and were detected only in the

fraction containing unbound virus and in the wash. In marked contrast, $Ad5F_{HI}FLAG$

10   particles efficiently bound to the M2-affinity gel, since viral DNA was present primarily

in the FLAG peptide eluate. Thus, establishing that the heterologous ligand sequence

engineered into the HI loop of the knob domain of the fiber incorporated in the intact Ad5

virion remains accessible for interaction with the relevant receptor structure, thereby

providing the rationale for the generation of genetically targeted adenovirus vectors on

15   this basis.

Any patents or publications mentioned in this specification are indicative of the

levels of those skilled in the art to which the invention pertains. These patents and

publications are herein incorporated by reference to the same extent as if each individual

20   publication was specifically and individually indicated to be incorporated by reference.

The present examples along with the methods, procedures, treatments, molecules,

and specific compounds described herein are presently representative of preferred

embodiments, are exemplary, and are not intended as limitations on the scope of the

invention.

33

While the foregoing description was directed to the preparation of some particular materials, it will be understood that in view of the teaching presented herein, one of skill in the art could readily prepare a variety of modified viral materials, all of which are within the scope of the present invention.

SEQUENCE LISTING

(1) GENERAL INFORMATION:

    (i)   APPLICANTS: David T. Curiel

    (ii)   TITLE OF INVENTION: METHOD FOR THE PURIFICATION
                                                      OF VIRUS

    (iii)   NUMBER OF SEQUENCES: 8

    (iv)   CORRESPONDENCE ADDRESS:
          (A)   ADDRESSEE: Ellen S. Cogen
                                     Gifford, Krass, Groh, Sprinkle, Patmore,
                                     Anderson & Citkowski, P.C.
          (B)   STREET: 280 N. Old Woodward Ave., Suite 400
          (C)   CITY: Birmingham
          (D)   STATE: Michigan
          (E)   COUNTRY: U.S.
          (F)   ZIP: 48009

    (v)   COMPUTER READABLE FORM:
          (A)   MEDIUM TYPE: Floppy disk
          (B)   COMPUTER: IBM
          (C)   OPERATING SYSTEM: Windows 95
          (D)   SOFTWARE: WordPerfect 6.1

    (vi)   CURRENT APPLICATION DATA:
          (A)   APPLICATION NUMBER:

43

Claims

1   1.   A method for purifying a gene therapy vector polypeptide, comprising the

2   steps of:

3   providing a vector capsid protein having a heterologous peptide sequence

4   expressed therein;

5   providing a reagent capable of selectively binding the heterologous peptide

6   sequence;

7   contacting said vector capsid protein with said reagent, so that said reagent binds

8   to said vector capsid protein; and

9   releasing said protein from said reagent.

1   2.   The method as in claim 1, wherein the sequence functions to ablate

2   tropism of a homologous fiber protein parent of said protein.

1   3.   The method as in claim 1, wherein said protein is a capsid constituent of

2   a protein coated gene therapy vector, said vector having a capsid surface.

1   4.   The method as in claim 3, wherein said sequence is exposed on the capsid

2   surface.

1   5.   The method as in claim 4, wherein said vector is an adenovirus.

1   6.   The method as in claim 5, wherein said vector is a recombinant

2   adenovirus.

1   7.   The method as in claim 3, wherein the sequence is present at a carboxy

2   terminus of said capsid constituent.

1   8.   The method as in claim 4, wherein the sequence is present in a knob

2   domain of said protein.

1   9.   The method as in claim 8, wherein the sequence is present in a H-I loop

2   of said knob domain.

1   10.   The method as in claim 3, wherein the sequence provides for said protein

2   to interact with other capsid constituents of said vector in a manner comparable with

3   interactions of said homologous fiber protein parent.

1   11.   The method as in claim 1, wherein said reagent is a monoclonal antibody.

1   12.   The method as in claim 1, wherein said reagent is immobilized within a

2   matrix.

1   13.   The method as in claim 1, wherein contacting said protein with said

2   reagent occurs within an affinity chromatography column.

1   14.   The method as in claim 1, wherein contacting said protein with said

2   reagent occurs at atmospheric pressure.

1   15.   The method as in claim 1, wherein releasing said protein occurs in

2   response to the presence of imadozole.

1   16.   A method for purifying an adenoviral vector, comprising the steps of:

2   providing an adenoviral vector having a capsid, wherein the capsid comprises: a

3   protein having a heterologous peptide sequence therein, the sequence exposed on a

4   surface of the capsid;

5   providing a reagent capable of selectively binding to the heterologous peptide

6   sequence;

7   contacting said vector with said reagent, so that said reagent binds to said vector;

8   and

9   releasing said vector from said reagent.

1   17.   The method as in claim 16, wherein the sequence allows said protein to

2   interact with the capsid so as to yield an identical quaternary structure for said protein,

3   as compared to a homologous protein fiber parent of said protein.

1   18.   The method as in claim 16, wherein the sequence functions to ablate

2   tropism of said homologous protein parent.

1   19.   The method as in claim 16, wherein the sequence is present at a carboxy

2   terminus of said protein.

46

1   20.   The method as in claim 16, wherein the sequence is present in a knob

2   domain of said protein.

1   21.   The method as in claim 20, wherein the sequence is present in a H-I loop

2   of the knob domain.

1   22.   A purified, immobilized gene therapy vector comprising:

2   a protein coated vector comprising: a nucleic acid sequence foreign to said

3   vector; a capsid having a surface, said capsid incorporating a protein; and said protein

4   having a heterologous polypeptide sequence therein, wherein the sequence is exposed on

5   the capsid surface so as to yield an identical quaternary structure for said protein, as

6   compared to a homologous protein fiber parent of said protein;

7   an antibody bound to the heterologous polypeptide sequence; and

8   a matrix conjugated to said antibody.

1   23.   The vector of claim 22, wherein said vector is adenovirus.

1   24.   The vector of claim 22, wherein the sequence is present at a carboxy

2   terminus of said protein.

1   25.   The vector of claim 22, wherein the sequence is present at a knob domain

2   of said protein.

1   26.   The vector of claim 25, wherein the sequence is present at a H-I loop of
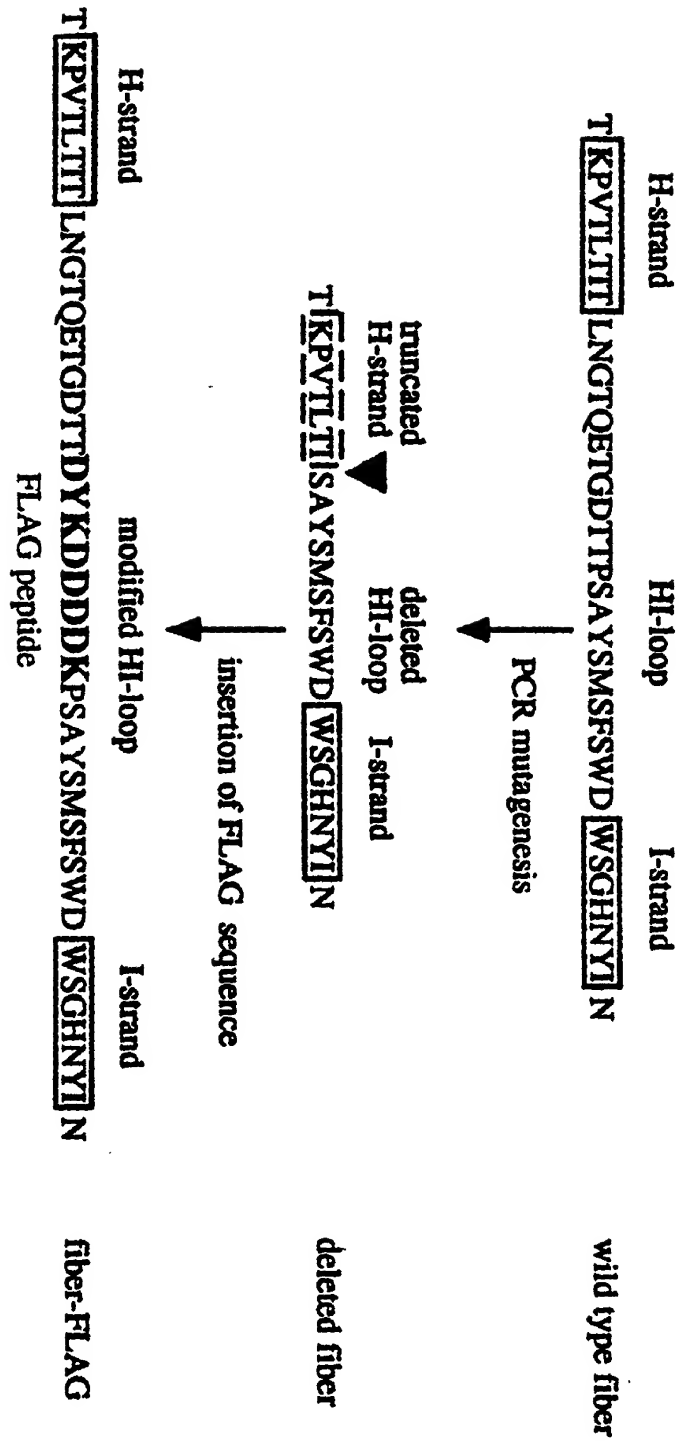

2   the knob domain.
